Scientific Coordinator: A. A. Raduta

Outline

- 1 Nuclear shapes
- 2 Triaxial Shapes
- 3 Wobbling motion
- 4 Theoretical formalism
- 5 Numerical application - energy spectrum
- 6 Conclusions

Nuclear Radius

The **shape** of the nucleus is most generally described in terms of the *nuclear radius*:

$$R(\theta, \varphi; t) = R_0 \left(1 + \sum_{\lambda=0}^{\infty} \sum_{\mu=-\lambda}^{\lambda} \alpha_{\lambda\mu}(t) Y_{\lambda}^{\mu}(\theta, \varphi) \right) \quad (1)$$

- The $\alpha_{\lambda\mu}$ are collective coordinates \implies *vibrations of the nucleus*.
- Y_{λ}^{μ} are the spherical harmonics.

Nuclear shapes

Most nuclei are spherical or axially symmetric in the ground state.

Figure 1: **Spherical:** $\beta_2 = 0$; **Prolate:** $\beta_2 > 0$; **Oblate:** $\beta_2 < 0$

Quadrupole deformations

- Most relevant vibrational degrees of freedom in nuclei.
- Play a crucial role in the rotational spectra of nuclei.

Quadrupole radius

For pure quadrupole deformations:

$$R(\theta, \varphi) = R_0 \left(1 + \sum_{\mu} \alpha_{2\mu} Y_2^{\mu}(\theta, \varphi) \right), \quad (2)$$

Using A. Bohr's description, the coordinates $\alpha_{2\mu}$ can be reduced to only two *deformation parameters*: β_2 (*eccentricity*) and γ (**triaxiality**).

Nuclear triaxiality

- Besides the axially symmetric shapes (i.e., spherical, prolate, and oblate), nuclei can be **triaxial** \implies lack of symmetry along any of the principal axes.
- The asymmetry is given by the non-zero value of γ .

Triaxial ellipsoid

Schematic example with a triaxial ellipsoid ($\gamma \neq 0$) $\beta_2 > 0$.

Figure 2: **Left:** side-view. **Right:** top view.

Nuclear triaxiality

- Probing triaxiality experimentally is a real challenge (e.g., large and complex detector setups).
- Only two fingerprints known so far: **chiral motion** (Frauendorf, 1997) and **wobbling motion** (Bohr and Mottelson, 1975).

Wobbling Motion (WM)

- Collective effect → *unique* to triaxial nuclei.
- Predicted almost 50 years ago, first experimental confirmation: in 2001 (Odegard et al.) for ^{163}Lu .
- In present, few wobblers are experimentally confirmed in the mass regions: $A \approx 130, 160, 180$ → A list of all known wobblers will be available in my PhD thesis (Chapter 3).

Triaxial nuclei

A triaxial nucleus can rotate about any of the three axes.

The rotational angular momentum (a.m.) is NOT aligned along any of the body-fixed axes \Rightarrow **precesses** and **wobbles** around the axes with the largest MOI.

Figure 3: Schematic representation for the nuclear wobbling motion.

Wobbling Bands

Wobbling bands

Sequences of $\Delta I = 2\hbar$ rotational bands that are built on different *wobbling phonon excitations* ($n_w = 0, 1, \dots$).

Oscillatory behavior, with a *tilting angle* for the angular momentum proportional to $n_w \longrightarrow$ **harmonic-like motion**.

Figure 4: Rotational-band structures of the wobbling motion.

- For ^{163}Lu : $n_w = 0, 1, 2, 3$ wobbling phonon numbers, respectively.
- Nuclei have **large** quadrupole moments
- **Strong E2** character for the electro-magnetic transitions.

Even-Even vs. Even-Odd Nuclei

Theoretical frameworks for **even-mass** nuclei

- ① *Harmonic Approximation(s)* (Bohr and Mottelson, 1975)
- ② Triaxial-Rotor-Model (Davydov and Filippov, 1958)
- ③ Boson-approximations (Tanabe, 1971)

Theoretical frameworks for **odd-mass** nuclei

- ① Particle Rotor Model (Hamamoto, 2002)
- ② Tilted-axis wobbling (Frauendorf and Meng, 1997)
- ③ RPA, Mean-Field Theories, GCM+AMP...

Recent work on wobbling motion

- RPA for ^{163}Lu , Raduta et al (PRC, 2017)
- Tilted-axis wobbling for ^{135}Pr , R. Budaca (PRC, 2018)
- PRM for ^{163}Lu , R. Poenaru (IJMPE, 2021)

Theoretical formalism - Even-Odd Nuclei

Based on the work: **AA Raduta, CM Raduta, R Poenaru, Journal of Physics G: Nuclear and Particle Physics 48 (1), 015106, 2020**

Description of WM for an even-odd nucleus

- one single-particle (nucleon) *coupled* to an *even-even* triaxial core.
- the nucleon is moving in a quadrupole deformed mean-field generated by the core
- particle + rotor coupling drives the entire system to large (and stable) deformations ($\epsilon \sim 0.2 - 0.4$).

Hamiltonian:

$$\hat{H}_{\text{rot}} = \sum_{k=1}^3 A_k \left(\hat{I}_k - \hat{j}_k \right)^2 . \quad (3)$$

$A_k \rightarrow$ inertia parameters: $A_k = (2\mathcal{I}_k)^{-1}$.

Theoretical Formalism - Rotational Hamiltonian

Expanding \hat{I}_2 up to first order (particle is *rigidly coupled* to the core):

$$\hat{I}_2 = I \left(1 - \frac{1}{2} \frac{\hat{I}_1^2 + \hat{I}_3^2}{I^2} \right), \quad (4)$$

can help re-write the initial Hamiltonian:

Rigid coupling Hamiltonian: $\mathbf{j} = (j \cos \theta, j \sin \theta, 0)$

$$\hat{H}_{\text{rot}} = \textcolor{red}{A} \textcolor{red}{H}' + \textcolor{blue}{H}_{sp} + \textcolor{violet}{s.t.}, \quad (5)$$

$$\textcolor{red}{H}' = \hat{I}_2^2 + u \hat{I}_3^2 + 2v_0 \hat{I}_1, \quad \textcolor{blue}{H}_{sp} = \sum_{k=1}^2 A_k \hat{j}_k^2, \quad \textcolor{violet}{s.t.} = A_1 I^2 - A_2 j_2 I, \quad (6)$$

$$1 > u = \frac{A_3 - A_1}{A} > -1, \quad v_0 - \frac{A_1 j_1}{A}, \quad A = A_2 \left(1 - \frac{j_2}{I} \right) > 0 \quad (7)$$

Rotational Hamiltonian

- H' looks like the Hamiltonian for a triaxial rigid rotator + constrained (cranked) to move along the 1-axis.
- The a.m. algebra is defined as:

$$\hat{I}_{\pm} = \hat{I}_2 \pm i\hat{I}_3, \quad \hat{I}_0 = \hat{I}_1, \quad (8)$$

$$[\hat{I}_-, \hat{I}_+] = 2\hat{I}_0, \quad [\hat{I}_{\mp}, \hat{I}_0] = \mp\hat{I}_{\mp}. \quad (9)$$

Hamiltonian + Schrodinger Equation

$$H' = a \left(\hat{I}_+^2 + \hat{I}_-^2 \right) + b \left(\hat{I}_+ \hat{I}_- + \hat{I}_- \hat{I}_+ \right) + c \hat{I}_0, \quad (10)$$

$$H' |\Psi\rangle = E |\Psi\rangle. \quad (11)$$

Angular Momentum Representation

The a.m. ladder operators are re-defined in terms of new variables $q, d/dq$:

$$\hat{I}_{\mp} = i \frac{c \pm d}{s} \left(I \mp \hat{I}_0 \right) , \quad \hat{I}_0 = Icd - s \frac{d}{dq} . \quad (12)$$

s, c, d are the **Jacobi Elliptic Functions**:

$$s = \operatorname{sn}(q, k) , \quad c = \operatorname{cn}(q, k) \quad (13)$$

$$d = \operatorname{dn}(q, k) , \quad (14)$$

The functions are periodic in q , with the periods $4K$ (s), $4K$ (c), and $2K$ (d).

Coordinate representation

The variable q is defined in terms of k ($0 < k^2 < 1$):

$$q = \int_0^\varphi (1 - k^2 \sin^2(t))^{-1/2} dt = F(\varphi, k) , \quad \varphi = F^{-1}(q, k) , \quad (15)$$

$$s = \sin \varphi , \quad c = \cos \varphi , \quad d = \sqrt{1 - k^2 s^2} , \quad k = \sqrt{|u|} . \quad (16)$$

New Hamiltonian

$$H' = -\frac{d^2}{dq^2} - 2v_0 s \frac{d}{dq} + I(I+1)s^2 k^2 + 2v_0 c d I , \quad (17)$$

with the associated *Schrodinger Equation* (fully separated Kinetic and Potential terms):

$$\left[\frac{d^2}{dq^2} + V(q) \right] \Psi = E \Psi \quad (18)$$

The "Elliptic" Potential

The expression of $V(q)$

With the elliptic functions s, c, d , and arbitrary k :

$$V(q) = [I(I+1)k^2 + v_0^2] s^2 + (2I+1)v_0cd = V(-q) . \quad (19)$$

Local minima states: meta-stable. *Deepest well* states: degenerate.

The "Elliptic" Potential

- The deepest minima appear at $q = 0, \pm 4K$.
- Meta-stable (local) minima appear at $q = \pm 2K$.

Bargmann Mapping - Boson description

The variables q and d/dq can be mapped to a pair of **boson operators** (b, b^\dagger) via the Bargmann representation of the angular momentum:

$$q \rightarrow b^\dagger, \quad \frac{d}{dq} \rightarrow b. \quad (20)$$

New angular momentum operators

This mapping leads to *the first boson expansion of the angular momentum components in literature*.

$$\hat{I}_+ = i \frac{cb^\dagger - db^\dagger}{sb^\dagger} \left(I + Icb^\dagger db^\dagger - sb^\dagger b \right), \quad (21)$$

$$\hat{I}_- = i \frac{cb^\dagger + db^\dagger}{sb^\dagger} \left(I - Icb^\dagger db^\dagger + sb^\dagger b \right), \quad (22)$$

$$\hat{I}_0 = Icb^\dagger db^\dagger - sb^\dagger b. \quad (23)$$

Harmonic oscillator

Expanding $V(q)$ around the deepest minima up to second order in q , the spectrum of H_{rot} is obtained:

$$E_n = A_1 I^2 - (2I + 1)A_1 j_1 - I A_2 j_2 + \sum_{k=1}^2 A_k j_k^2 + \hbar\omega \left(n + \frac{1}{2} \right) . \quad (24)$$

- The frequency $\hbar\omega$ is the so-called *wobbling frequency*.

$$\hbar\omega_I = f(A_1, A_2, A_3; I) \quad (25)$$

- n is the wobbling phonon number $n = 0, 1, \dots$

Wobbling spectrum

- Recall H_{rot} contains the H' Hamiltonian.
- The $\hbar\omega$ frequency corresponds to H_{rot} .
- Similarly, $\hbar\omega'$ is the frequency for E'_n , corresponding to H' .

Figure 5: $j = 13/2$, $I = 55/2$.

Numerical Results

- Find the excitation energies for a nucleus using the obtained analytical results E_n .
- Applied the formalism on the wobbling spectrum of ^{135}Pr .
- Experimental confirmation for three wobbling bands (Matta et al. 2015).

Fitting procedure

- Moments of inertia $\mathcal{I}_{1,2,3}$ are set as free parameters.
- Angle θ is also a free variable.
- ^{135}Pr ($Z = 59$, $N = 76$) has $j = 11/2$ (proton from the $h_{11/2}$ orbital).
- **Fitted Mol:** $\mathcal{I}_1 : \mathcal{I}_2 : \mathcal{I}_3 = 91 : 9 : 51 [\hbar\text{MeV}^{-1}]$.
- **Fitted θ :** -119 degrees (-2.07694 rad).
- $E_{\text{rms}} = 0.170$ MeV.

Excitation Energies

Elliptic potential

- Contribution coming from the wobbling frequency is rather small.
- Potential exhibits local minima and deep minima.
- Stability of the wobbling motion is characterized by $q \sim 3 - 4$ rad.

- The Hamiltonian for an odd-mass nucleus H_{rot} is described based on the coupling between *triaxial even-even core* and an odd particle.
- H_{rot} is split up in three terms: H' , H_{sp} , and a spin term.
- Treating H' through the variables $q, d/dq$, one obtained a Schrodinger equation with separated kinetic and potential terms.
- The potential term $V(q)$ is expressed in terms of the Jacobi elliptic functions s, c, d .
- Bargmann mapping changes the a.m. components to boson operators.
- Expansion of $V(q)$ up to second order in q is used to obtain E_n .
- Spectrum of ^{135}Pr is described, reproducing the energies for the three wobbling bands.

Thank you for your attention!
